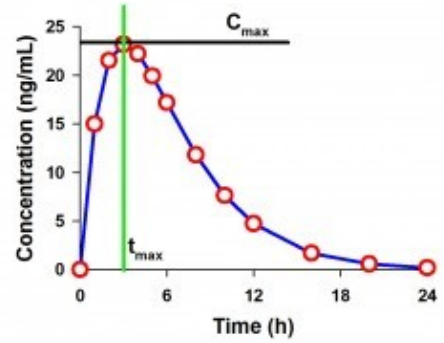
U.S. FOOD & DRUG ADMINISTRATION

Clinical Pharmacology:
Concepts to Support Drug Development



Shirley K. Seo, Ph.D.
Director, Division of Clinical Pharmacology III
Office of Clinical Pharmacology/OTS/CDER/FDA

FDA Clinical Investigator Training Course

November 14, 2018

Disclaimer

- The opinions contained in this presentation are my own and do not necessarily represent the views of the FDA.

Objectives

- Defining clinical pharmacology
- Clinical pharmacology studies:
  - Timing
  - Goals
  - Key design elements
  - Information gained from these studies
- Learn about typical clinical pharmacology properties that are characterized for a drug
- Labeling examples of the impact of clinical pharmacology studies

How do Clinical Pharmacologists Contribute to the Drug Development Process?

We "own the dose"

- Help determine the dosing regimen of a drug
  - How much to give?
  - How often to give it?
- Help determine if the dose of a drug needs to be adjusted due to various intrinsic/extrinsic factors

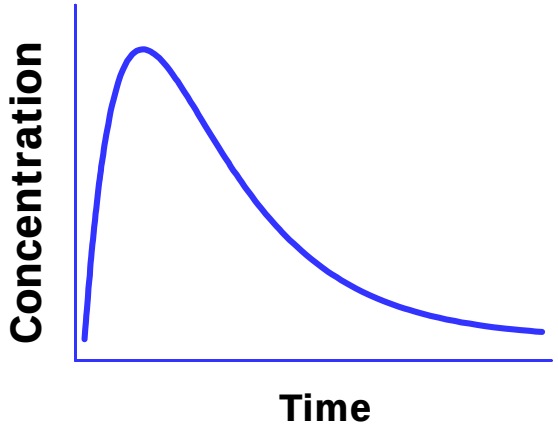
Right drug?
Right dose?
Right time?

Right patient?

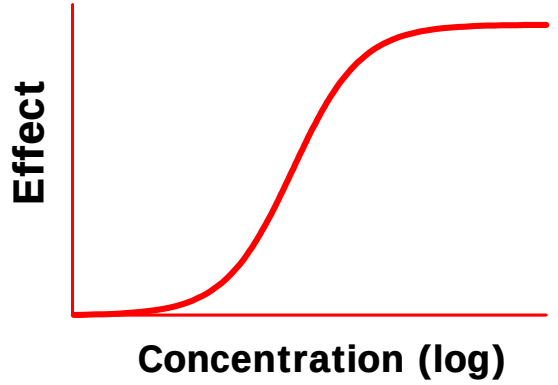
Clinical Pharmacology—What is it?

- Study of the Pharmacokinetics (PK) and Pharmacodynamics (PD) of a drug in humans

PK: what the body does to the drug
(Absorption, Distribution, Metabolism, Excretion)

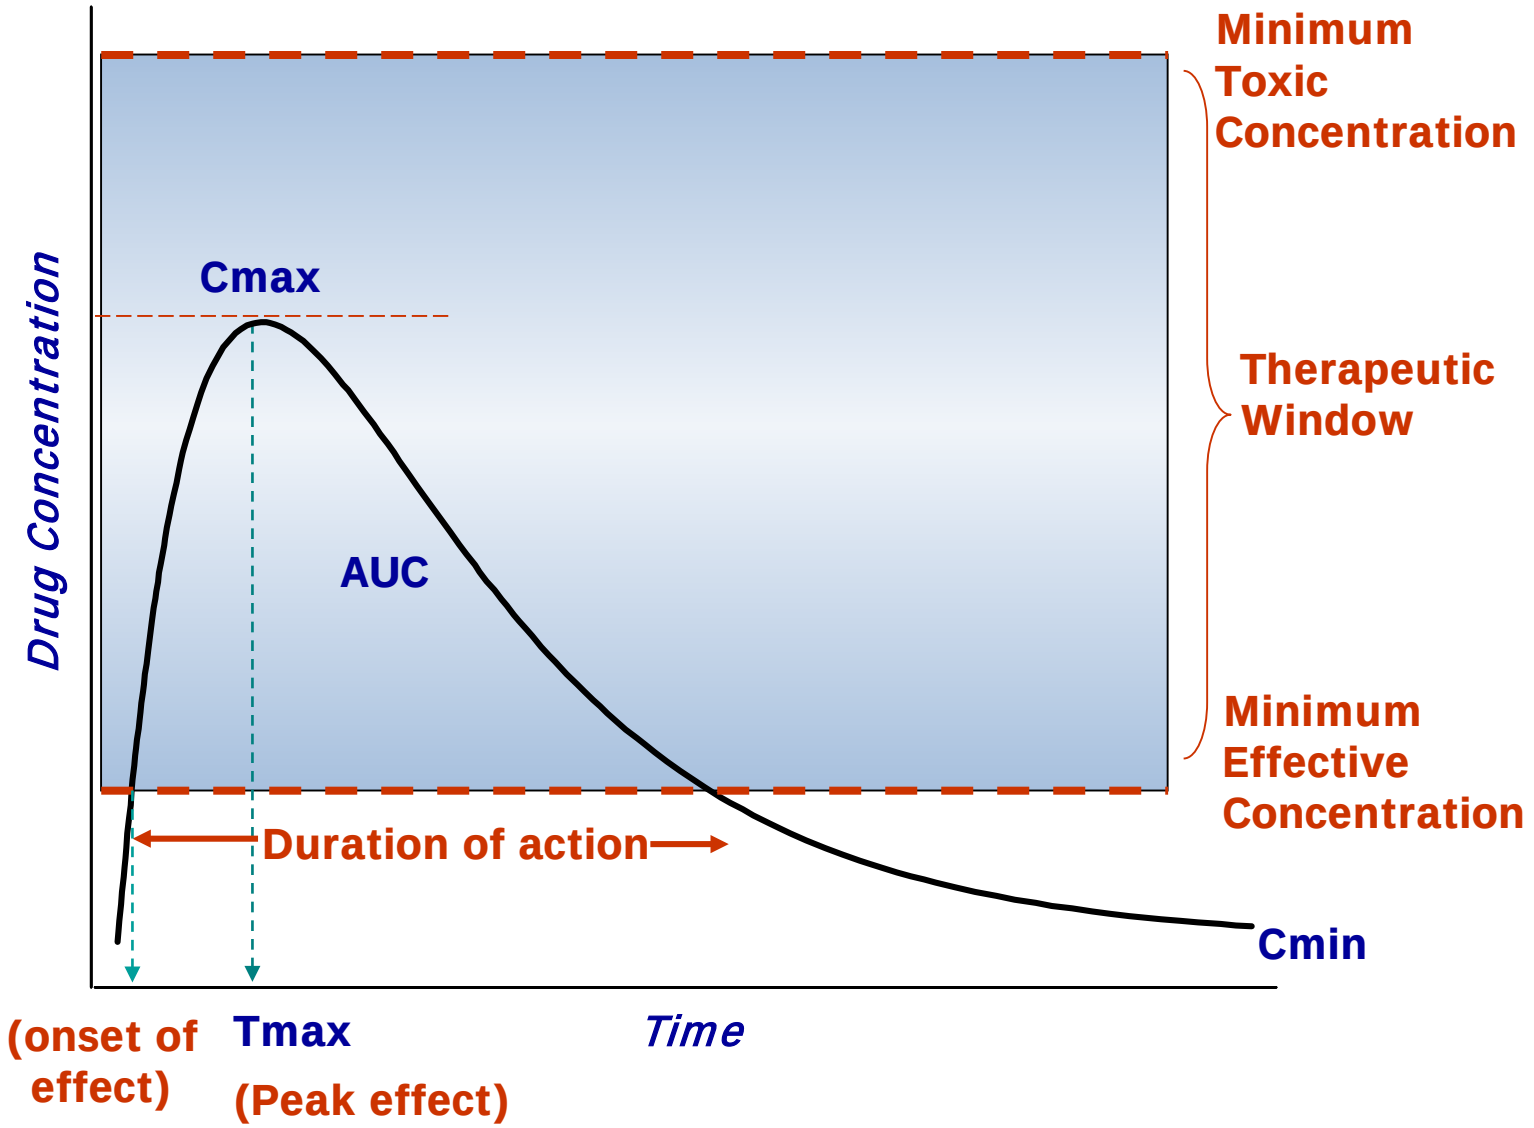


PD: what the drug does to the body



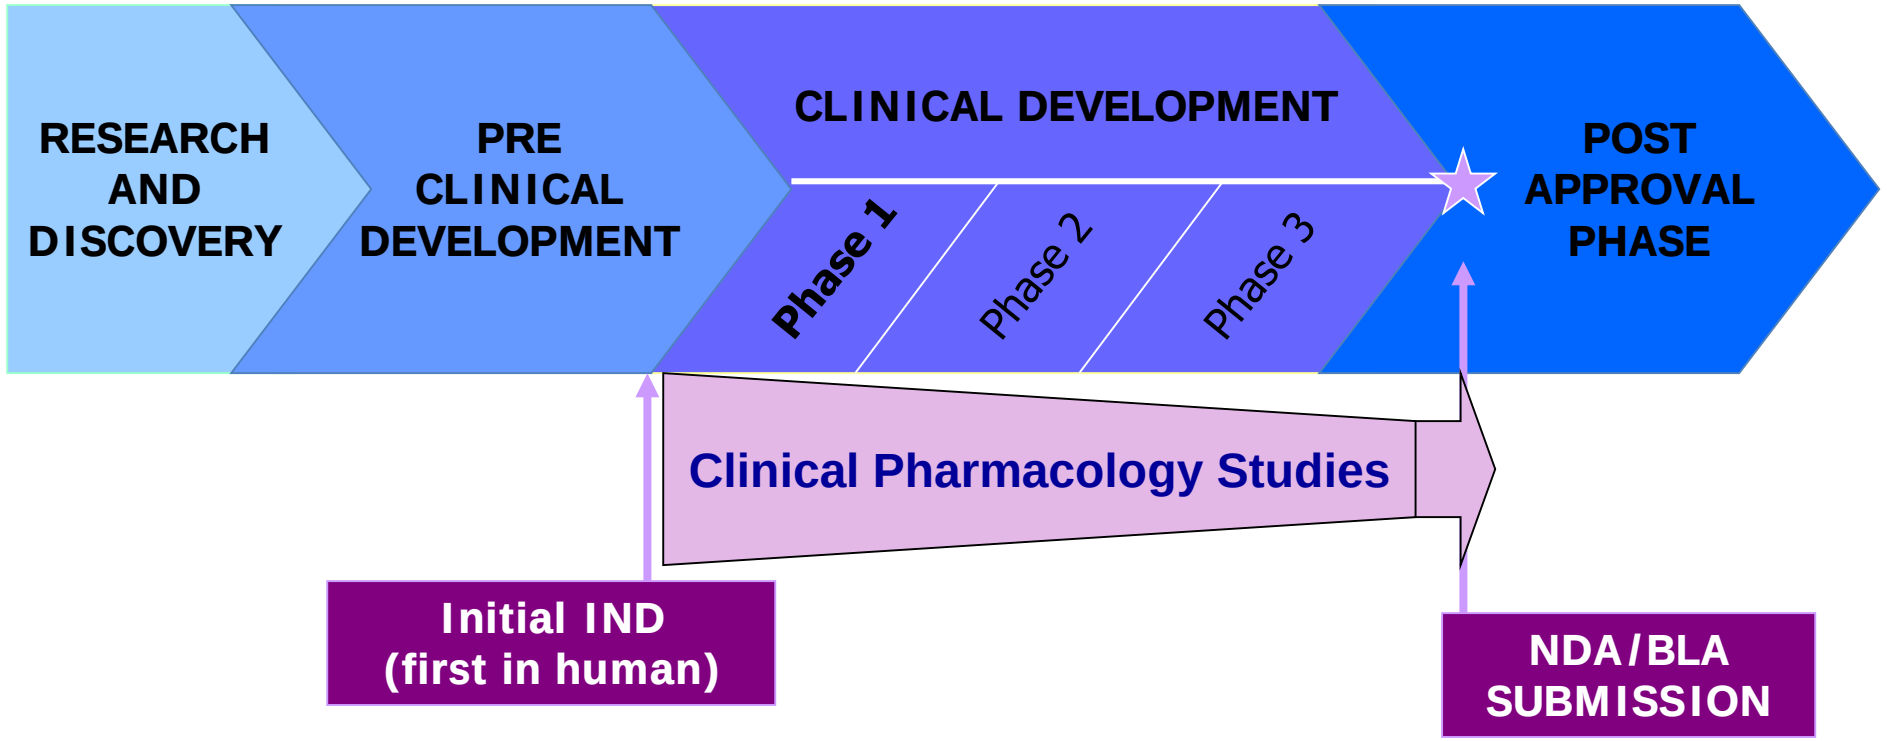
Commonly referred to as an exposure-response (ER) profile

PK and Drug Effect



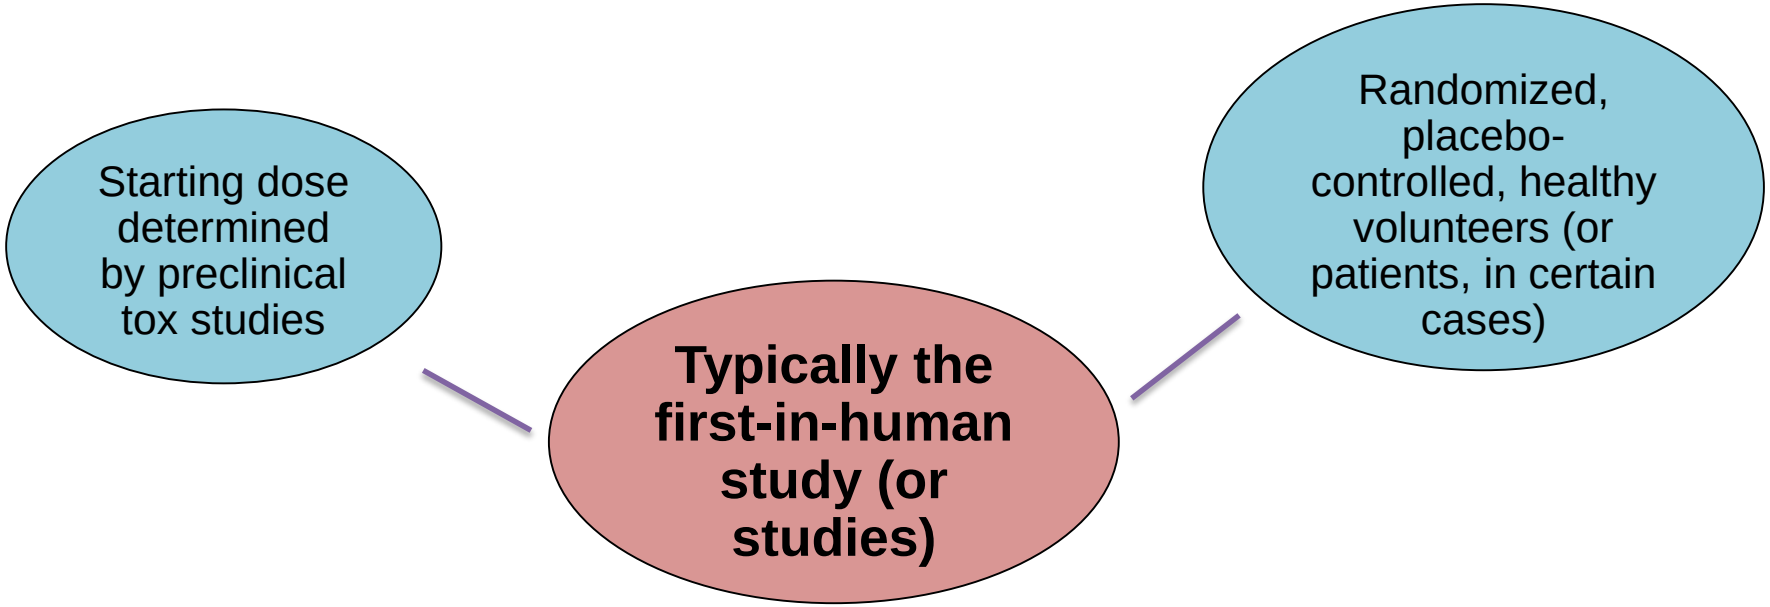
Clinical Pharmacology Studies

Timing



Early phase studies are designed mainly to investigate the safety/tolerability (if possible, identify MTD) and pharmacokinetics of an investigational drug in humans

First-in-Human Study



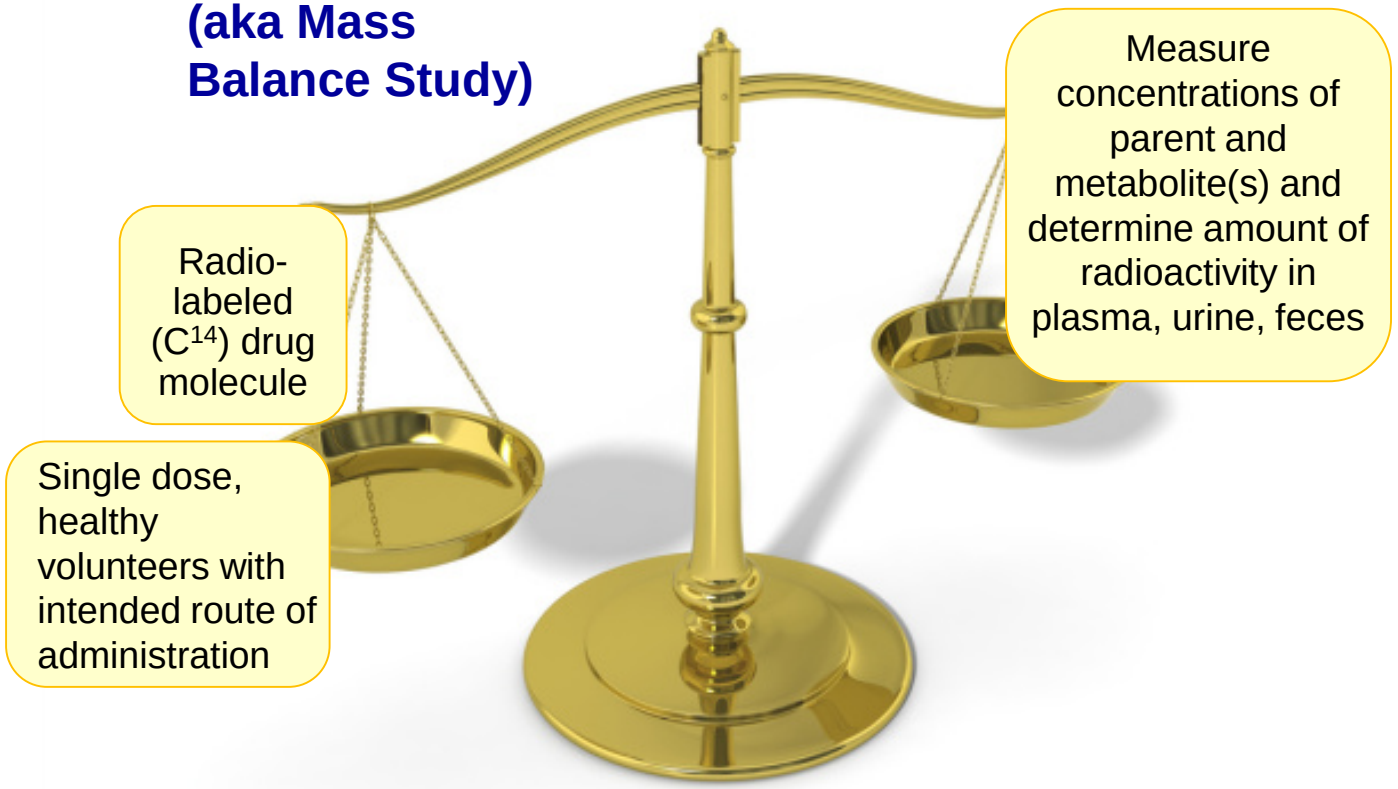
Information gained:

-Safety/tolerability, identify maximum tolerated dose
-General PK characteristics, variability, linearity, dose proportionality
-Steady-state parameters
-Preliminary exploration of drug elimination

ADME (Absorption, Distribution, Metabolism, Excretion) Study

(aka Mass Balance Study)

Objective: To understand the full clearance mechanisms of the drug and its metabolites in humans



Information gained:

-Primary mechanism(s) of metabolism and excretion from the body

-Proportion of parent drug converted to metabolite(s)

Bioavailability (BA) Studies

- Objective: To evaluate the rate (Cmax, Tmax) and extent (AUC) of absorption of drug from a test formulation (vs. reference formulation)

- Typically crossover, single dose study in healthy subjects; measure extent and rate of absorption of parent drug and major active metabolites (if any)
  - Can assess relative (one formulation vs. another) or absolute (vs. IV formulation) bioavailability

Information gained:

-Comparison of amount of drug that reaches systemic circulation from each tested formulation

Food Effect Study

Objective: To evaluate the effect of food on rate and extent of drug absorption from a given formulation

- Single dose study in healthy subjects using highest strength of drug product[1].
- Fed state should be FDA high-fat high-calorie meal (other meals can also be studied)
- PK assessments similar to BA study
- No food effect if 90% CI of fed/fasted Cmax and AUC ratios within 80-125%.
- The clinical significance of any observed food effect would be determined based on drug's exposure-response profile.

Information gained:

-How to administer drug in clinical trials

-Labeling instructions on how to administer drug with respect to food

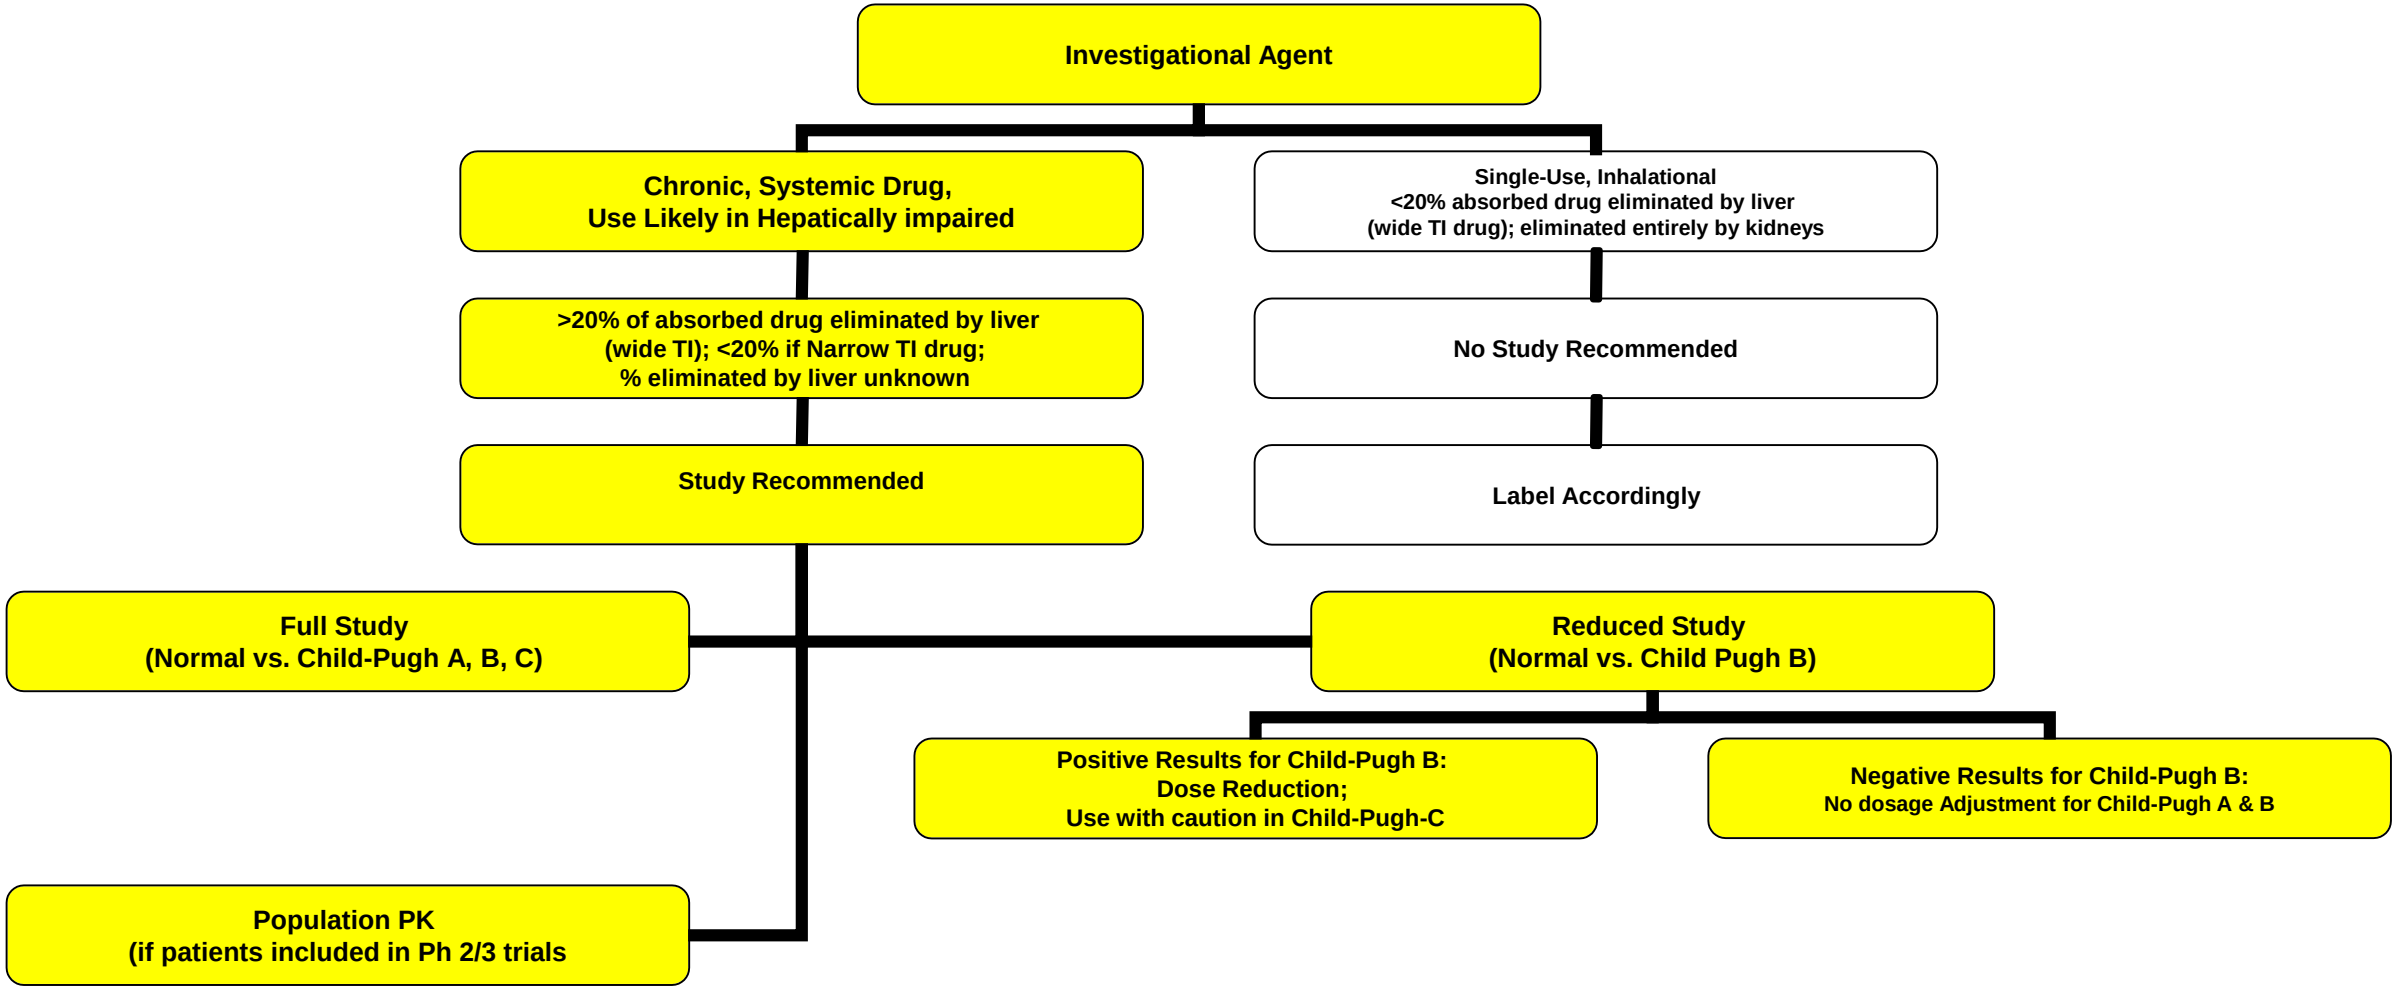
Hepatic Impairment Study Decision Tree



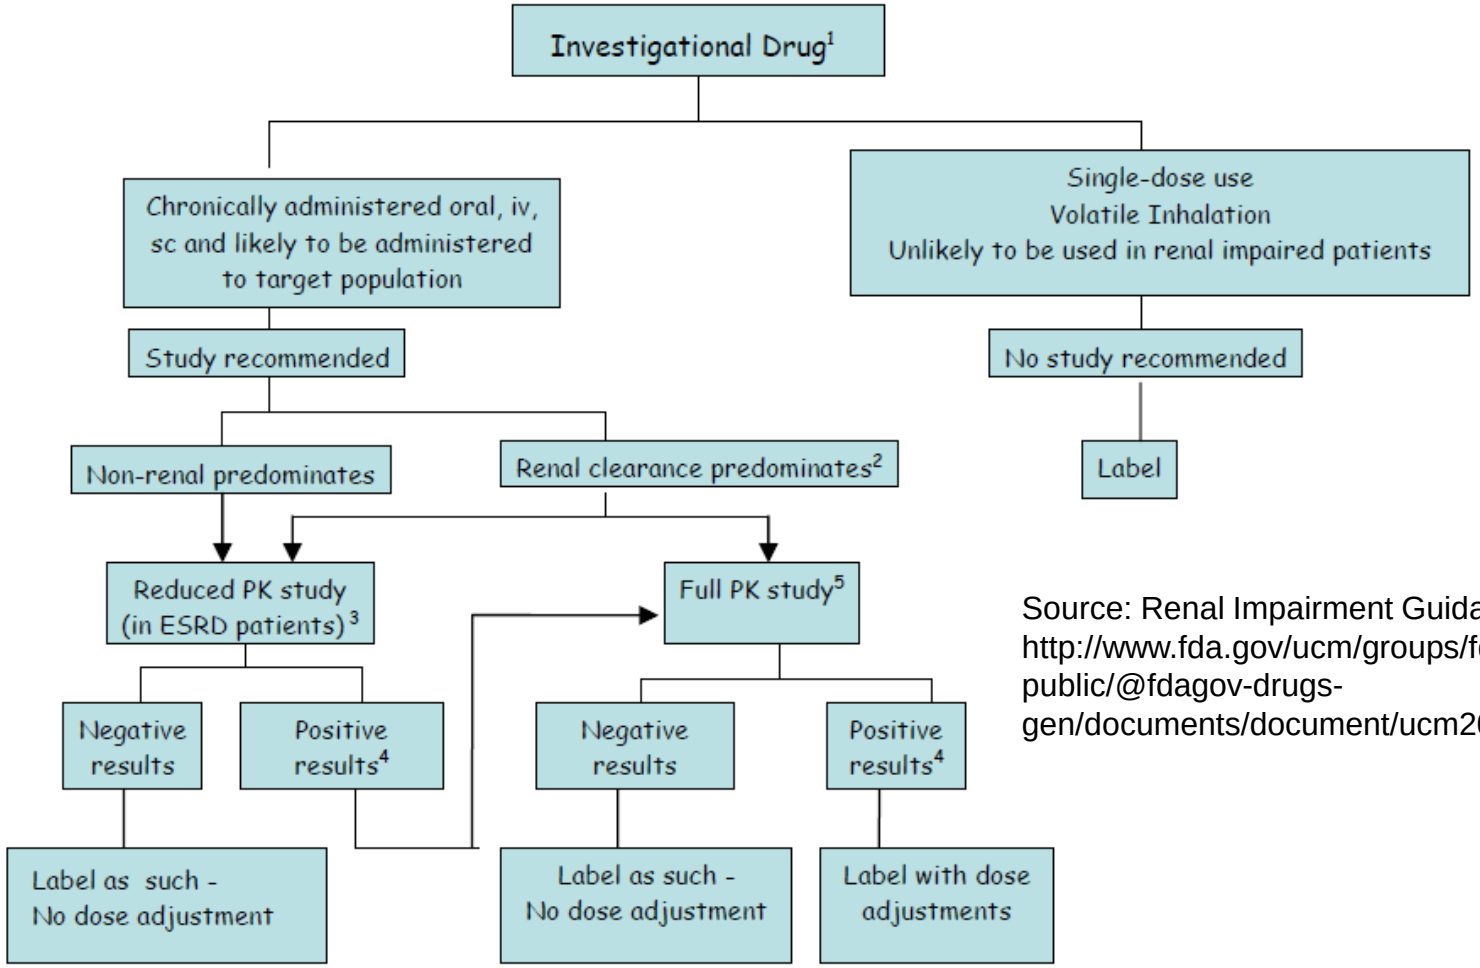
[1]Source: Hepatic Impairment guidance (2003): http://www.fda.gov/ucm/groups/fdagov-public/@fdagov-drugs-gen/documents/document/ucm072123.pdf

Hepatic Impairment Study

- **Study Designs:**
- Full study design: Single dose, parallel groups, males & females with varying degrees of hepatic impairment (≥6 per group)
  - Normal Hepatic Function (matched for age, sex, & BW to subjects with hepatic impairment)
  - Child-Pugh Class A (Mild)
  - Child-Pugh Class B (Moderate)
  - Child-Pugh Class C (Severe)
- Reduced study design: Normal vs. Child-Pugh B (Moderate) (≥8 per group)
- Pop-PK approach (pre-planned analysis):
  - Should include patients w/ varying degrees of hepatic impairment in phase 2 and 3 trials
  - Should include appropriate evaluation of severity of liver disease

Information gained:
-Effect of hepatic impairment on PK of parent drug and metabolites
-Dosage recommendations for various stages of hepatic impairment

Renal Impairment Study Decision Tree



Source: Renal Impairment Guidance (2010): http://www.fda.gov/ucm/groups/fdagov-public/@fdagov-drugs-gen/documents/document/ucm204959.pdf

1. Metabolites (active/toxic) follow the same decision tree.
2. The sponsor has the option of conducting a reduced study in ESRD patients or a full study.
3. To be conducted in ESRD patients not yet on dialysis
4. The results are "positive" when the PK changes are clinically significant based on exposure-response of the drug
5. See section IV.B for the full PK study design, or additional studies can be conducted including a population PK evaluation

Renal Impairment Study

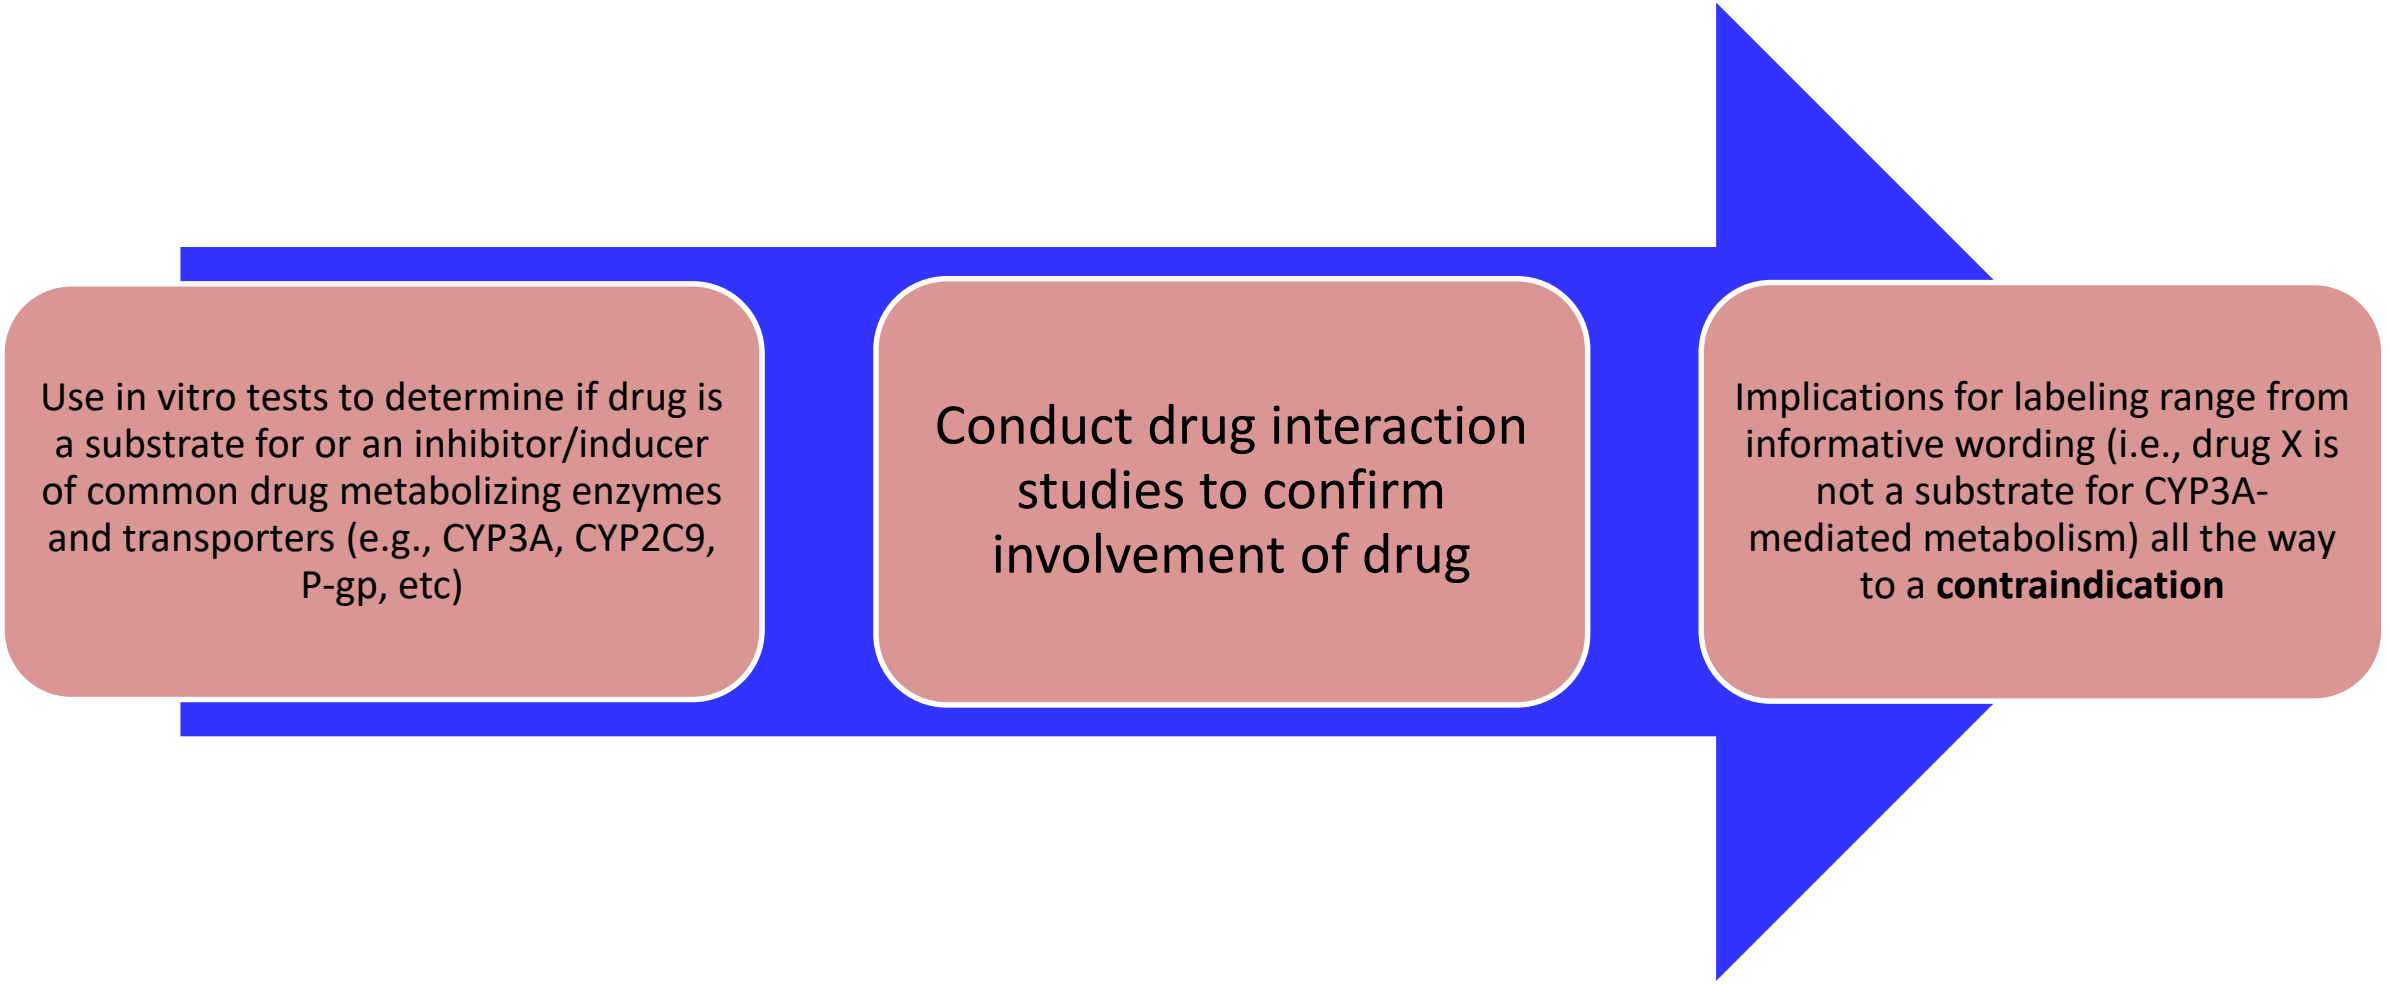
- **Study designs:**
- Full study design:
- Generally single dose, parallel groups, “healthy” males and females with varying degrees of renal function (≥6 per group, based on CrCl):
  - Normal (≥90 mL/min)
  - Mild (60-89 mL/min)
  - Moderate (30-59 mL/min)
  - Severe (15-29 mL/min)
  - ESRD (<15 mL/min) dialysis and non-dialysis
- Reduced study design:
- Same general design as full, except only study severes and normals
- Pop-PK approach
- Include appropriate number of subjects in each impairment group

Information gained:

-Effect of renal impairment on drug clearance; dosage recommendations for various stages of renal impairment

-Effect of hemodialysis (HD) on drug exposure; info on whether dialysis could be used as treatment for drug overdosage

Drug Interaction Studies



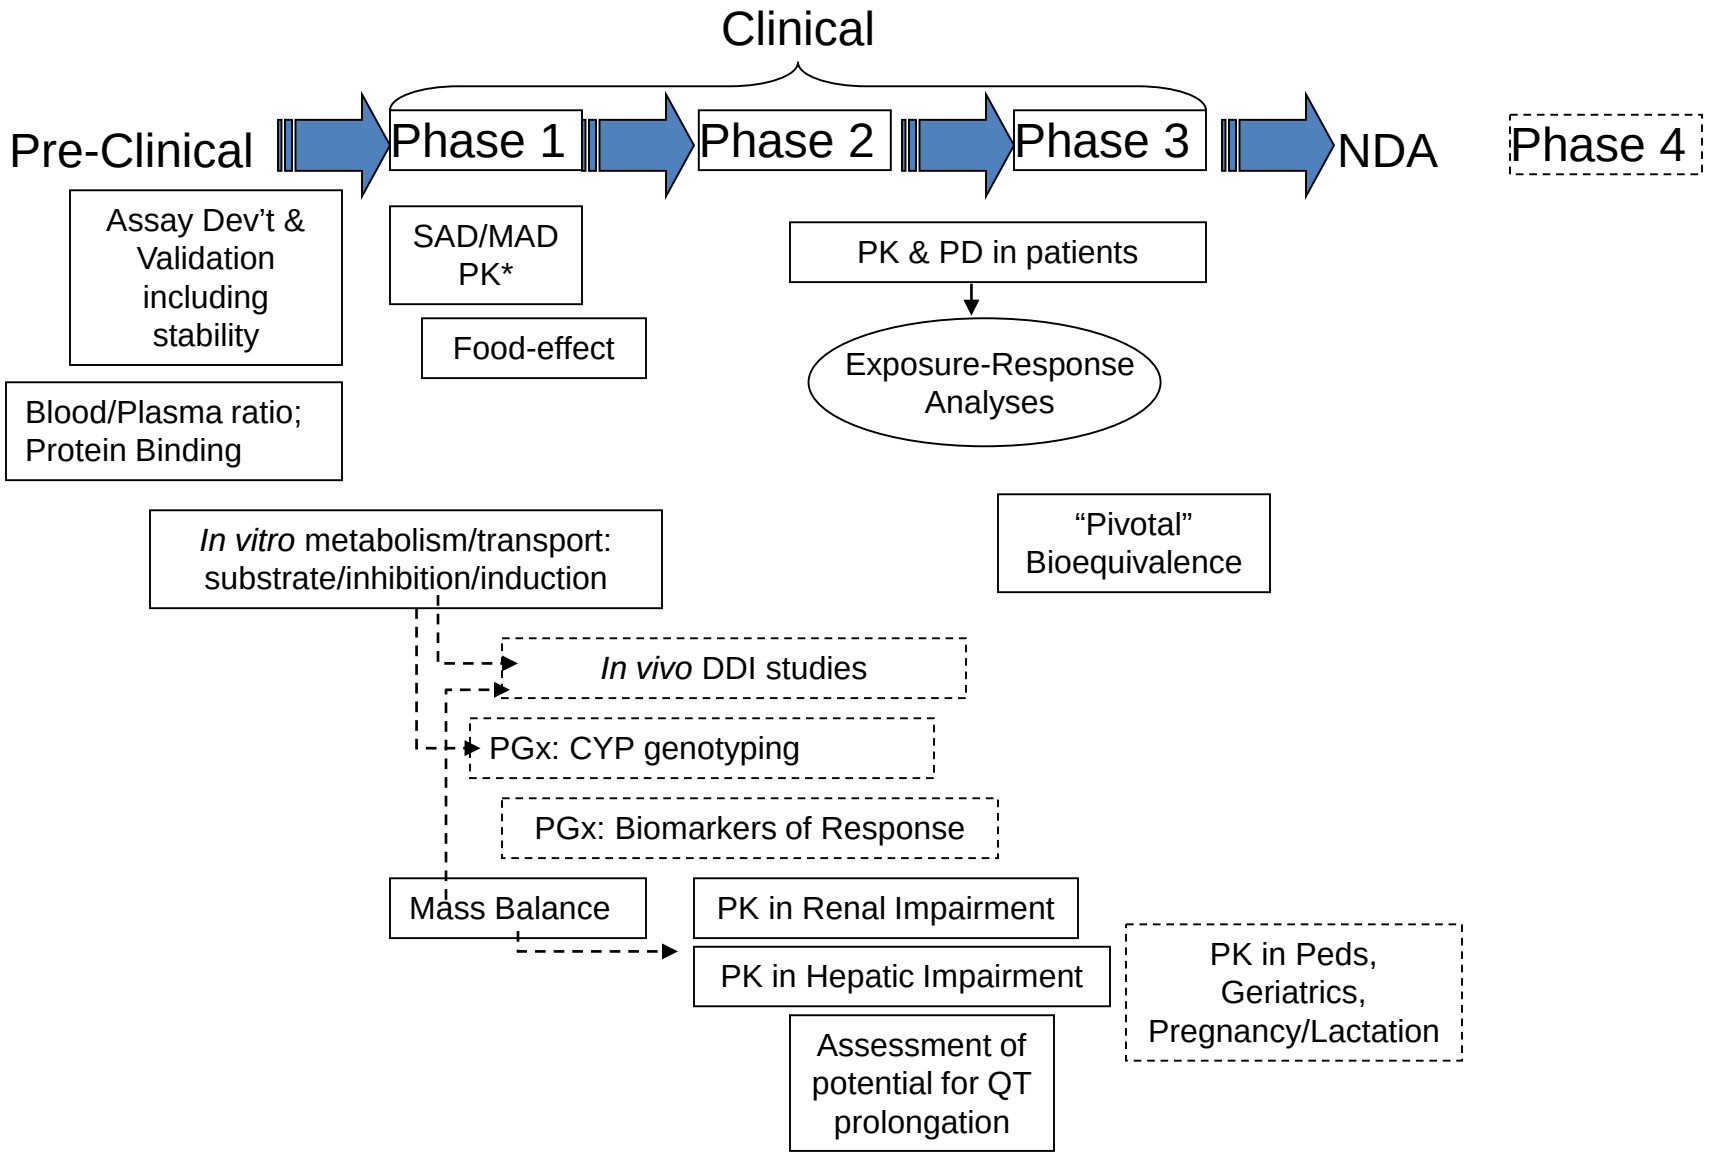
Additional detailed information can be found in the Guidance for Industry: Clinical Drug Interaction Studies — Study Design, Data Analysis, and Clinical Implications (2017)

Drug Interaction Studies

Some key points to consider:

- Several factors should be taken into account to maximize the possibility of detecting an interaction (and also be clinically relevant):
  - Dose of inhibitor/inducer
  - Route(s) of administration
  - Timing of co-administration
  - Number of doses
- Degree of effect (inhibition/induction) is typically classified by change in the substrate AUC:
  - e.g., Drug causes ≥ 5-fold increase in midazolam AUC → "potent" inhibitor of CYP3A4
- Exposure-response information on the drug is important in assessing the clinical significance of the change in AUC of substrate by inhibitor/inducer.

Timing of Early and Clinical Pharmacology Studies



What do we need to know?

Clinical Pharmacology Properties of a Drug

- **ABSORPTION:**
  - What is the bioavailability and PK variability?
  - Does it exhibit linear PK (e.g. dose-proportional increases in Cmax & AUC) or accumulate over time?
    - Will impact the design of some studies
  - Is exposure significantly affected by concomitant food, pH-altering medications, grapefruit, alcohol, etc?
  - Is absorption affected by transporters?

Clinical Pharmacology Properties of a Drug

- **DISTRIBUTION:**
  - Does drug reach the target site(s) of action immediately and at effective/nontoxic concentration? Does it accumulate in non-target organs?
  - Does it bind to plasma proteins? Is the extent of protein binding concentration- or time-dependent?
    - only free or unbound drug is active
    - PK in terms of total drug concentrations often sufficient (e.g., in PK studies in renal and hepatic impairment)
  - CSF and others

Clinical Pharmacology Properties of a Drug

- **METABOLISM/EXCRETION:**
  - Is it metabolized by a CYP or other enzyme?
  - Is CL variable and dependent on ‘covariates’ such as age, race, gender, disease/comorbidities?
  - Is CL time-dependent (e.g., metabolic auto-induction, diurnal variation)?
    - May affect duration or timing of studies for PK profiling

Clinical Pharmacology Properties of a Drug

- **OTHERS:**
  - A Narrow Therapeutic Index Drug?
    - If yes, slight changes in drug exposure may significantly impact efficacy/safety
    - May require therapeutic drug monitoring in clinical trials and clinical practice to minimize toxicities and lack of efficacy
  - A significant inhibitor or inducer of CYP enzymes or transporters?
    - If yes, further drug interaction evaluation may be needed

Important Exposure Parameters of a Drug

Parent Drug and Active Metabolites:

- T_{max}
  -represents the most appropriate time(s) to perform safety assessments (e.g., vital signs, ECG, other immediate PD effects)
- t½
  - considered when determining dosage interval
  - related to time to steady state (t_{ss}) after dose initiation or dose adjustment; considered in evaluating need for a loading dose
  - influences the duration of monitoring after dosing and follow-up after withdrawal of therapy
  - determines adequate washout period between treatments (in crossover studies)
- Cmax, Cmin, AUC
  - important for dose selection (eg. PK/PD parameters predicting efficacy of anti-infective drugs)

The impact on labeling

Phase 1 Studies: Impact on Labeling

FULL PRESCRIBING INFORMATION:

Food Effect Example:
REYATAZ® (atazanavir) oral capsules

- Administration of a single dose of atazanavir (800 mg) with a light meal increased Cmax by 57% and AUC by 70%; a high-fat meal increased AUC by 35% with no change in Cmax. The %CVs of AUC and Cmax decreased by approximately one-half compared to the fasting state.

- Clinical trials were conducted under fed conditions.

Label directs administration with food.

Source: http://www.accessdata.fda.gov/drugsatfda_docs/label/2016/021567s039,206352s004lbl.pdf

Renal Impairment Example:
DORIBAX® (doripenem) powder for IV use

- In an ADME study, ~93% of the dose was excreted in urine by 12 hours.
- Because doripenem is primarily eliminated by the kidneys, a full PK study in patients with renal impairment was conducted. The study demonstrated a significant difference in PK between patients with moderate and severe renal impairment compared to those with normal renal function. Also, 52% of the dose was recovered in the dialysate following dialysis.
- In Phase 2/3 trials, dosage was adjusted based on CrCL.

The label recommends dosage reduction for patients with moderate or severe renal impairment… and hemodialysis as a treatment for overdosage.

Source: http://www.accessdata.fda.gov/drugsatfda_docs/label/2015/022106s015lbl.pdf

Hepatic Impairment Example:
ISENTRESS® (raltegravir) oral tablets

- A mass balance study showed that raltegravir is eliminated primarily by glucuronidation in the liver. Renal clearance is a minor pathway of elimination.
- In the hepatic impairment study (reduced study design), there were no clinically significant pharmacokinetic differences between subjects with moderate hepatic impairment and healthy subjects.
- PopPK analysis of Phase 2/3 trial data further indicates that the PK of raltegravir in Child Pugh B patients were not different from patients with normal hepatic function.

Labeling states: No dosage reduction for patients with moderate or mild hepatic impairment is recommended. The effect of severe hepatic impairment on the PK of the drug was not studied.

To Summarize, Clinical Pharmacology Studies…

- Are conducted to gain a fundamental understanding of the pharmacokinetics (PK; exposure) and the pharmacodynamics (PD; biologic effect) of the drug.
- Provide useful information for the design of Phase 3 clinical trials (e.g., using dose-response and exposure-response analyses).
- Inform patient care
  - identification of appropriate dosing regimen(s) in relevant patient subpopulations
